

Abstract

(NO)WEB HYPERTEXT SYSTEM IN EMACS (WHYSE) is an integrated development environment for Noweb and \LaTeX within Emacs, similar to EDE but not sharing development principles. It is based off of an academic paper written in 1991 by Brown and Czejdo. A paper describing this implementation—written in Noweb and browsable, editable, and auditable with WHYSE, or readable in the printed form—is hoped to be submitted to The Journal of Open Source Software (JOSS) before the year 2024. N.B.: the paper will include historical information about literate programming, and citations (especially of those given credit in the «Commentary» for ideating WHYSE itself).

Users of WHYSE in Emacs are expected to be familiar with Noweb; this does not include how Noweb is built from source (that is arcane, supposedly). It may, however, include the writing of filters implemented with Sed, AWK, or other languages. Users must know how to write a custom command-line for noweave (read the manual section regarding the `-v` option). If you only know how to call the noweave command you’re reading the wrong document. Read the Noweb manual first, please. Developers of WHYSE extensions should read the Noweb Hacker’s Guide until they understand it, afterwards reading this documentation several times until the full implementation is understood. I recommend modifying the system using itself to keep organized, and writing literately; you’ll thank yourself later for doing so.

1 Projects

The organization of this literate program is *linear*, with aspects of the program explained as the user would encounter them, more or less. A user will read from the package description that they should call an interactive command to create a project. The WHYSE application has a single interactive command: `whyse`. The command loads the first element of the customization variable `w-registered-projects`, considering that the default project, or it opens the “Easy Customization Interface” (`M-x customize`): an effective prompt to enter the necessary information.

A customization group for WHYSE is defined to organize its customization variables, and these details are explained before moving on to explain the struct used during runtime.

```
1 (Customization and global variables 1)≡ (20a) 3b>
  (defgroup whyse nil
    "noWeb HYpertext System in Emacs"
    :tag "WHYSE"
    :group 'applications)

  (defcustom w-registered-projects nil
    "This variable stores all of the projects that are known to WHYSE."
    :group 'whyse
    :type '(repeat w-project-widget)
    :require 'widget
    :tag "WHYSE Registered Projects")

  (defvar w-parse-success t
    "The success or failure of the last parsing of noweb tool syntax.")

Defines:
  w-parse-success, used in chunk 8b.
  w-registered-projects, used in chunk 3a.
  whyse, used in chunks 18 and 23.
```

The `w-project-widget` type used for the registered projects variable is a simple list widget containing the name of the project and its Noweb source file, along with a filename for a shell script which generates the Noweb tool syntax for this project. Each Noweb project has a different command-line, and some are complex enough to have a makefile, or multiple makefiles! Noweb itself is an example of that level of complexity. The shell script is later executed by WHYSE upon loading the project, and the standard output captured for parsing by a PEG parser.

```
2 <Widgets 2>≡ (20a)
(define-widget 'w-project-widget 'list
  "The WHYSE project widget type."
  :format "\n%v\n"
  :offset 0
  :indent 0

  ;; NOTE: the convert-widget keyword with the argument
  ;; 'widget-types-convert-widget is absolutely necessary for ARGS to be
  ;; converted to widgets.
  :convert-widget 'widget-types-convert-widget
  :args '((editable-field
            :format "%t: %v"
            :tag "Name"
            :value ""))

    (file
      :tag "Noweb source file (*.nw)"
      :format "%t: %v"
      :valid-regexp ".*\\.nw$"
      :value "")

    (string
      :tag "A shell command to run a shell script to generates Noweb tool syntax"
      :format "%t: %v"
      :documentation "A shell script which will produce the
Noweb tool syntax. Any shell commands involved with
noweave should be included, but totex should of course
be excluded from this script. The script should output
the full syntax to standard output. See the Noweb
implementation of WHYSE for explanation."
      :value "")))
```

An example of what the list generated from the information entered into Customize would look like is given here for elucidation (as it would exist in a custom-set-variables form).

```
'(w-registered-projects
  '(("noWeb HYpertext System in Emacs"
    "~/Desktop/whyse.nw"
    "make -C ~/Desktop --silent --file ~/src/whyse/Makefile tool-syntax"))
  nil
  (widget))
```

```
3a  (WHYSE 3a)≡ (20a)
      (defun whyse ()
        (interactive)
        (if-let ((w-load-default-project?)
                  (default-project (cl-first w-registered-projects))
                  (project (make-w-project :name (cl-first default-project)
                                           :noweb (cl-second default-project)
                                           :script (cl-third default-project)))))
          (progn (convert the noweb document to tool syntax and parse it with the peg 4b)
                  ;; TODO: define the following chunks.
                  ;; «compile the parse tree into DDL and send it to the database»
                  ;; «create the atomic window layout and insert the navigation widgets»
                  )
          (open Customize to register projects 3c)))
```

Defines:

whyse, used in chunks 18 and 23.

Uses w-load-default-project? 3b and w-registered-projects 1.

WHYSE is likely to be useful for very large literate programs, so the command is designed to initialize from an existing project without prompt. In more verbose terms: unless w-load-default-project? is non-nil and w-registered-projects includes at least one element, Customize will be opened to customize the WHYSE group when whyse is invoked.

```
3b  (Customization and global variables 1)+≡ (20a) <1
      (defcustom w-load-default-project? t
        "Non-nil values mean the system will load the default project.

        nil will cause the interactive command 'whyse' to open Customize on
        its group of variables."
        :type 'boolean
        :group 'whyse
        :tag "Load default project when 'whyse' is invoked?")
```

Defines:

w-load-default-project?, used in chunk 3.

```
3c  (open Customize to register projects 3c)≡ (3a)
      (message
        "No WHYSE projects registered, or 'w-load-default-project?' is nil. %s"
        (customize-group 'whyse))
      Uses w-load-default-project? 3b.
```

4a *⟨WHYSE project structure 4a⟩*≡ (20a)

```
(cl-defstruct w-project
  "A WHYSE project"
  ;; Fundamental
  name
  noweb
  script
  database-file
  database-connection

  ;; Usage
  frame

  ;; Metadata
  (date-created (current-time-string))
  date-last-edited
  date-last-exported

  ;; TODO: limit with a customization variable so that it does not grow too large.
  history-sql-commands)
```

Instances of this struct are only initialized with a few values: name, noweb, and script. The rest of the fields either have default values dependent upon the input data (like the database-file, database-connection, and date-created), or are given values when appropriate later in operation (such as date-last-exported) or upon initialization (frame).

Initialization when the interactive command is called is covered next; to summarize: w-project-load-hook is run.

2 System initialization from new projects

To summarize this section, since it is longer than the previous section, the object is to *⟨convert the noweb document to tool syntax and parse it with the peg 4b⟩*, which is thus the name of a code chunk used in whyse.

In more explicit words, this section describes the actions that occur when a user invokes whyse interactively (with *M-x*) and the preconditions have been met; the whyse function has already been introduced, and only the “meaty” business end of its operation has been left undefined until now. Ergo, *⟨convert the noweb document to tool syntax and parse it with the peg 4b⟩* gathers together the functionality that converts a Noweb to its tool syntax with a project’s specified shell script, and parses the text before the next section of body forms is executed. Those send the parsed text to the database, and finally create the atomic window for the IDE in the active frame.

4b *⟨convert the noweb document to tool syntax and parse it with the peg 4b⟩*≡ (3a)

```
(with-temp-buffer
  (insert (shell-command-to-string (w-project-script project)))
  (goto-char (point-min))
  (message "Noweb parse:\n%S" (w-parse-current-buffer-with-rules)))
```

Uses w-parse-current-buffer-with-rules 8b.

2.1 Database initialization

TODO finish the creation of a database. Use what I learned in the fall!

Every project should have a database file located somewhere within the user's Emacs directory; if the user is a Spacemacs user, then Spacemacs' cache directory is used, otherwise the database is made in the user's Emacs directory and not a sub-directory thereof.

The form used to create the absolute path for the location of the database joins three things: the user's Emacs directory, nil or Spacemacs' cache directory, and the name of the project with ".db" appended. Note that concatenating nil with a string is the same as returning the string unchanged.

```
5a <return a filename for the project database 5a>≡ (5b)
      (file-name-concat
        ;; Usually ~/.emacs.d/
        user-emacs-directory
        ;; 'nil' or the Spacemacs cache directory.
        (when (f-directory? (expand-file-name ".cache" user-emacs-directory))
          ".cache")
        ;; PROJECT-NAME.db
        (concat (w-project-name project)
          ".db"))
```

For SQLITE, the path name of the database to connect to or create is sufficient to establish a connection, so the next step is to connect to the database and store the connection object in the appropriate slot of the project struct.

```
5b <create the database 5b>≡
      (setf (w-project-database-connection project)
        (emacs-sqlite
          (w-project-database-file <return a filename for the project database 5a>)))
```

The only thing left to do is establish the schema of the tables, which is done by mapping over several EMACSQL s-expressions.

```
6 <map over SQL s-expressions, creating the tables 6>≡
  (mapcar (lambda (expression)
            (emacsql (w-project-database-connection project)
                     expression))

;; A list of SQL s-expressions to create the tables.
'[:create-table module
  ([module-name
   content
   file-name
   section-name
   (displacement integer)
   (module-number integer :primary-key)]]]

[:create-table parent-child
  ([ (parent integer)
    (child integer)
    (line-number integer)]
    (:primary-key [parent
                   child]))]

[:create-table identifier-used-in-module
  ([identifier-name
   (module-number integer)
   (line-number integer)
   type-of-usage]
   (:primary-key [identifier-name
                  module-number
                  line-number
                  type-of-usage]))]

[:create-table topic-referenced-in-module
  ([ (topic-name nil)
    (module-number integer)]
   (:primary-key [topic-name
                  module-number])))]
```

Figure 1: Simple drawing of WHYSE frame layout

2.2 Frame creation and atomic window specification

A frame like in Figure 1 should be created.

```
7 <Get project frame 7>≡
  (progn
    (select-frame (w-project-frame project))
    (switch-to-buffer (generate-new-buffer (w-project-name project))
      nil
      'force-same-window)
    (let* ((window-right (split-window-right))
           (parent-window (window-parent window-right)))
      (window-make-atom parent-window)
      (display-buffer-in-atom-window
        (get-buffer-create (format "Module Index<%s>"
                                   (w-project-name project)))
        ((window . ,parent-window) (window-height . 8))))))
```

3 Parsing

This section covers the parsing of the Noweb tool syntax produced by a project shell script (described in SECTION SIGN HERE 1). The following blocks of LISP code use the PEG Emacs Lisp package to provide for automatic parser generation from a formal PEG grammar based off of the exhaustive description given in the Noweb Hacker's Guide.

3.1 PEG rules

Every character of an input text to be parsed by parsing expressions in a PEG must be defined in terminal rules of the formal grammar. The root rule in the grammar for Noweb tool syntax is the appropriately named `noweb` rule. Beginning with-peg-rules brought into scope, the root rule `noweb` is ran on the buffer containing the tool syntax produced by the project shell script.

The grammar can be broken into five sections, each covering some part of parsing.

```
8a  <PEG rules 8a>≡ (8b)
    <high-level Noweb tool syntax structure 8c>
    <files and their paths 9b>
    <chunks and their boundaries 10>
    <quotations 12e>
    <keyword definitions 13a>
    <meta rules 9a>
```

```
8b  <buffer parsing function 8b>≡ (20a 23)
    ;;; Parsing expression grammar (PEG) rules
    (defun w-parse-current-buffer-with-rules ()
      "Parse the current buffer with the PEG defined for Noweb tool syntax."
      (with-peg-rules
        (<PEG rules 8a>)
        (let (w-peg-parser-within-codep)
          (peg-run
            (peg noweb)
            (lambda (lst)
              (setq w-parse-success nil)
              (pop-to-buffer (with-current-buffer
                              (generate-new-buffer "<WHYSE Parse failure log>")
                              (insert (format "PEXes which failed:\n%S" lst))
                              (current-buffer))))))))))
```

Defines:

`w-parse-current-buffer-with-rules`, used in chunks 4b and 23.

Uses `w-parse-success` 1 23.

As stated, the `noweb` rule defines the root expression—or starting expression—for the grammar. The tool syntax of Noweb is simply a list of one or more files, which are each composed of at least one chunk. Ergo, the following *<high-level Noweb tool syntax structure 8c>* is defined.

```
8c  <high-level Noweb tool syntax structure 8c>≡ (8a)
    ;;; Overall Noweb structure
    (noweb (bob) (not header) (+ file) (not trailer) (eob))
```

It is a fatal error for WHYSE if the header or trailer wrapper keywords appear in the text it is to parse. They are totally irrelevant, and only matter for the final back-ends (T_EX, L^AT_EX, or HTML) that produce human-readable documentation.

The grammar needs to address the fact that the syntax of the Noweb tool format is highly line-oriented, given the influence of AWK on the design and usage of Noweb (a historical version was entirely implemented in AWK). The following *meta rules 9a* define rules which organize the constructs of a line-oriented, or data-oriented, syntax.

9a *meta rules 9a* ≡ (8a)

```
;; Helpers
(nl (eol) "\n")
(!eol (+ (not "\n") (any)))
(spc " ")
```

TODO: Review the following paragraph and rephrase it.

With the *meta rules 9a* enabling easier definitions of what a given “keyword” looks like, the concept of a file needs to be defined. A file is “anything that looks like a file to Noweb”. However, by default, only the chunk named “*” (it’s chunk header is «*») is tangled when no specific root chunk is given on the command line.

TODO: Write about the need for the overall document to be separate from the one-or-more files specified in the document. Exempli gratia: the current document, contained in `whyse.el` and `test-parser-with-temporary-buffer.el`. If these two files were tangled at the same time, such that the output file discovery ability of Noweb was used, then there would be more than one file in the intermediate tool syntax, but still a single preceding documentation chunk before the first file, and a single succeeding documentation chunk after the last file.

9b *files and their paths 9b* ≡ (8a)

```
;; Technically, file is a tagging keyword, but that classification only
;; makes sense in the Hacker’s guide, not in the syntax.
(file (bol) "@file" spc (substring path) nl
  (list (and (+ chunk) (* nwnl)
    (list (or (and x-chunks i-identifiers)
      (and i-identifiers x-chunks)))))
  ;; Trailing documentation chunk and new-lines
  (opt chunk)
  (opt (+ nl)))
‘(path chunk-list - (list path chunk-list))
(path (opt (or ".." ".") (* path-component) file-name)
  (path-component (and path-separator (+ [word])))
  (path-separator ["\\"/"])
  (file-name (+ (or [word] "."))))
```

NOTE: Writing PEXes for matching file names was the most difficult part I have encountered so far, as it has forced me to understand that a first reading of documentation is usually not sufficient to understand a complex library in an area of programming I have not practiced in before (language parsing).

Because chunks must not overlap, but can nest, the beginnings of chunks need to be pushed to the parsing stack and the end of a chunk needs to be popped off of it. The stack pushing operations in `kind` and `ordinal` delimit chunks by their kinds and number, and the stack actions in the `end` rule check that the chunk-related tokens on the stack are balanced.

```
10 <chunks and their boundaries 10>≡ (8a) 11a▷
(chunk begin (list (* chunk-contents)) end)
(begin (bol) "@begin" spc kind
  ;; (action (message "A chunk was entered; kind: %s" (cl-first peg-stack)))
  spc ordinal (eol) nl
  (action (if (string= (cl-second peg-stack) "code")
    (setq w-peg-parser-within-codep t))))
(end (bol) "@end" spc kind
  ;; (action (message "A chunk was exited; kind: %s" (cl-first peg-stack)))
  spc ordinal (eol) nl
  (action (setq w-peg-parser-within-codep nil))
  '(kind-one ordinal-one keywords kind-two ordinal-two -
    (if (and (= ordinal-one ordinal-two) (string= kind-one kind-two))
      ;;; Push the contents of the chunk to the stack in a cons
      ;;; cell with the car being a list of the kind and number.
      ;;; E.g.:
      ;; (("code" 3) . (@text @nl @text @nl))
      (cons (cons kind-one ordinal-one) keywords)
      (error "There was an issue with unbalanced or improperly nested chunks.")))
  (ordinal (substring [0-9] (* [0-9])))
  '(number - (string-to-number number)))
(kind (substring (or "code" "docs"))))
```

Valid chunk-contents is somewhat confusing, because chunks can contain many types of information other than text and new lines. The definition of what is valid follows.

1. text
2. nl
3. defn *name*
4. use *name*
5. line *n*
6. language *language*
7. index ...
8. xref ...

Any other keywords are invalid inside a code block. An example of an invalid keyword is anything related to quotations! *This restriction only applies to code blocks, however, and documentation chunks may contain quotations, of course.* As an exception, the keywords were originally banned inside code chunks, but to parse the noweb document in which WHYSE itself was written it needed to be adjusted. The grammar should be studied again to ensure that textual description and reality are in step.

11a $\langle \text{chunks and their boundaries 10} \rangle + \equiv$ (8a) $\langle 10 \text{ 12c} \rangle$

```

(chunk-contents
(or
  (structural keywords 11c)
  (tagging keywords 12a)
  x-notused
  (tool errors 12b)))

```

It is easier to handle the fatal keyword appearing inside chunks when it is a permissible keyword to appear inside a chunk; this allows the parser to consider a chunk with fatal inside of it *as a valid chunk*, but that does not mean that a chunk with a fatal keyword inside it does not invalidate a Noweb, it still does: the fatal keyword causes a fatal crash in parsing regardless. Those structural keywords which may be used inside the contents of a chunk are given next.

11b $\langle \text{structural keywords (except quotations) 11b} \rangle \equiv$ (11c)

```

;; structural
text
nwnl ;; Noweb's @nl keyword, as differentiated from the rule nl := "\n".
defn
use ;; NOTE: related to the 'identifier-used-in-module' table.

```

All structural keywords, then, are:

11c $\langle \text{structural keywords 11c} \rangle \equiv$ (11a)

```

(structural keywords (except quotations) 11b)
quotation

```

12a *<tagging keywords 12a>*≡ (11a)

```
;; tagging
line
language
;; index
i-define-or-use
i-definitions
;; xref
x-prev-or-next-def
x-continued-definitions-of-the-current-chunk
i-usages
x-usages
x-label
x-ref
```

12b *<tool errors 12b>*≡ (11a)

```
;; error
fatal
```

The fundamental keywords are text and nwnl (new line, per Noweb convention). Text keywords contain source text, and any new lines in the source text are replaced with the appropriate number of nwnl keywords (per convention).

12c *<chunks and their boundaries 10>*+≡ (8a) <11a 12d>

```
(text (bol) "@text" spc (substring (* (and (not "\n") (any)))) nl
      '(txt - (list 'text txt)))
(nwnl (bol) (substring "@nl" nl))
```

Nowebs are built from chunks, so the definition and usage of (i.e. references to) a chunk are important keywords.

12d *<chunks and their boundaries 10>*+≡ (8a) <12c>

```
(defn "@defn" spc (substring !eol) nl
  '(name - (cons "chunk" name)))

(use (bol) "@use" spc (substring !eol) nl
  '(chunk-name - (if chunk-name
                    (cons "Chunk usage (child)" chunk-name)
                    (error "UH-OH! There's a syntax error in the tool output!"))))
```

Documentation may contain text and newlines, represented by @text and [@nwnl]. It may also contain quoted code bracketed by @quote . . . @endquote. Every @quote must be terminated by an @endquote within the same chunk. Quoted code corresponds to the construct in the noweb source.

12e *<quotations 12e>*≡ (8a)

```
(quotation (bol) "@quote" nl
  (action (when w-peg-parser-within-codep
              (error "The parser found a quotation within a code chunk. A @fatal should have been
                    (substring (+ (and (not "@endquote") (any))))
                    ;; (list (* (or text nwnl defn use i-define-or-use x-ref)))
                    (bol) "@endquote" nl
                    '(lst - (cons "Quotation" lst))))
```

13a *<keyword definitions 13a>*≡ (8a) 13b>
 (line (bol) "@line" spc (substring ordinal) nl
 '(o - (cons "@line" o)))

 (language (bol) "@language" spc (substring words-eol))

The indexing and cross-referencing abilities of Noweb are excellent features which enable a reader to navigate through a printed (off-line) or on-line version of the literate document quite nicely. These functionalities each begin with a rule which matches only part of a line of the tool syntax since there are many indexing and cross-referencing keywords. The common part of each line is a rule which merely matches the @index or @xref keyword. The rest of the lines are handled by a list of rules in index-keyword or xref-keyword.

The *Noweb Hacker's Guide* lists these two lines in the “Tagging keywords” table, indicating that it’s unlikely (or forbidden) that the index or xref keywords would appear alone without any subsequent information on the same line.

@index ... Index information.
 @xref ... Cross-reference information

There are many keywords defined by the Noweb tool syntax, so they are referenced in this block and defined and documented separately. Some of these keywords are delimiters, so they are not given full “keyword” status (defined as a PEX rule) but exist as constants in the definition of a rule that defines the grouping.

13b *<keyword definitions 13a>*+≡ (8a) <13a
 ;; Index
<indexing and cross-referencing set-off words 13c>
<fundamental indexing keywords, which are restricted to within a code chunk 14a>
<the index of identifiers 14d>
<unsupported indexing keywords 15a>

 ;; Cross-reference
<cross-referencing keywords 15b>

 ;; Error
<error-causing keywords 16a>

Further keywords are categorized neatly as Indexing or Cross-referencing keywords, so they are contained in subsections.

3.2 indexing

Indexing keywords, both those used within chunks and those used outside of chunks, are defined in this section. The «fundamental indexing keywords, which are restricted to within a code chunk», index definitions or usages of identifiers and track the definitions of identifiers in a chunk and the usages of identifiers in a chunk. They may seem redundant, but are not; the *Noweb Hacker's Guide* offers a better explanation of the differences.

13c *<indexing and cross-referencing set-off words 13c>*≡ (13b)
 (idx (bol) "@index" spc)
 (xr (bol) "@xref" spc)

14a *<fundamental indexing keywords, which are restricted to within a code chunk 14a>*≡ (13b)

```
(i-define-or-use
  idx
  (substring (or "defn" "use")) spc (substring !eol) nl

  "\n")

```

4 Processing lists into SQL

This section covers how the parsed text generated in the last section is processed, creating a series of SQL statements that will be executed by SQLite using the interface provided by the EmacsSQL package.

First, the overall structure of the parsed text should be diagrammed. The parse tree is a list of noweb documents, each being a list themselves. The first atom of an inner list, corresponding to a document, is the filename of that document (hopefully the same filename as passed on the command-line elsewhere when the document is used).

Deeper, each document-list contains as the second atom a list of all of its contents, which is an association list thereof. Each association in the alist should be self-explanatory.

```

((noweb-document-one ((0 . ()))
  (1 . ())))
(noweb-document-two ((0 . ()))
  (1 . ())))

```

There are many steps to compiling the parse tree into SQL that can be directly executed by the backend database engine, so to *<compile the parse tree into DDL and send it to the database 16c>* is a multi-step process.

```

16c <compile the parse tree into DDL and send it to the database 16c>≡
<collapse text and newline tokens into their largest possible form 17b>
<push the compiled SQL to the database and to the history stack 18a>

```

The output tool syntax of notangle, and the parse tree resulting from the PEG, contain individual text tokens for fragments of whole text lines and form feed characters. These tokens exist because the cross-referencing tokens fragment the text lines, and new lines in the noweb document are treated specially to facilitate this fragmentation. The parsed from of the tool syntax is shown in this example from a development version of WHYSE.

```
(text " and \\textsc{Noweb}'s \\texttt{finduses.nw}!")
"@nl"
(text "\\end{enumerate}")
"@nl"
(text "")
"@nl"
```

In this development version it was not fully decided how tokens and the data they correspond to should be arranged, so the newlines are not part of a list, while the text characters are part of an outer plist of which the parentheses are not visible in this example.

To collapse these tokens into a single text token the peg-stack must be manipulated carefully. It isn't advisable to manipulate this variable in the course of a PEG grammar's actions, however, there is a use case for it when the previous rules and actions won't accomodate the necessary action without refactoring a larger part of the grammar. In this development version that is not a goal; basic functionality is sought after, not robustness or beauty.

w-nth-chunk-of-nth-noweb-document retrieves the parse tree for the nth noweb document, which in the case of whyse.nw is the parse tree of the zeroth-indexed document. It's quite a simple function. To obtain a given chunk of this document from the parse tree the result of the function is called with nth and the index of the chunk.

17a *(functions for navigating WHYSE parse trees 17a)*≡

```
(defun w-nth-document-file-name (nth-document parse-tree)
  "Return the file name of the nth-indexed document in the parse tree.

For the first document in the parse tree, that is the
zeroth-indexed document."
  (cl-first (nth nth-document parse-tree)))

(defun w-nth-document (nth-document parse-tree)
  "Return the subtree of the nth-indexed document in the parse tree."
  (cl-second (nth nth-document parse-tree)))

(defun w-nth-chunk-of-nth-document (nth-chunk nth-document parse-tree)
  "Return the subtree for the nth chunk of the nth-indexed document in the parse tree.

For the fifth chunk in the ninth document, that is the
4th-indexed chunk in the 8th-indexed document in the parse tree."
  (nth nth-chunk (cl-second (nth nth-document parse-tree))))

Defines:
w-nth-chunk-of-nth-document, never used.
w-nth-document, never used.
w-nth-document-file-name, never used.
```

17b *(collapse text and newline tokens into their largest possible form 17b)*≡

(16c)

```

18a <push the compiled SQL to the database and to the history stack 18a>≡ (16c)
;; NOTE: the result of evaluating the SQL is pushed to the history stack
;; alongside the SQL that was executed.
(cl-pushnew (cons (emacscl (w-project-database-connection default-project)
                        compiled-parse-tree)
                  . compiled-parse-tree)
            (w-project-history-sql-commands default-project))

```

5 Packaging

Installing an Emacs Lisp package is quite easy if the system is distributed through the GNU Emacs Lisp Package Archive (GNU ELPA), and only slightly less easy if it is distributed through MELPA (Milkypostman’s Emacs Lisp Package Archive). Other package archives have existed, but they are all ephemeral. The most popular alternative to GNU ELPA, Non-GNU ELPA, and MELPA is direct distribution of files through Git servers and the use of a package by the end user to install directly from such.

This software is in-development, so it will only be distributed directly through Git.

WHYSE follows the form of “simple”, single-file packages documented in the Emacs Lisp Reference Manual. The package file, `whyse.el`, is emitted by `notangle` which is called by the Makefile in every target but `clean`. All source development occurs in `whyse.nw` using `POLYMODE`.

The makefile distributed alongside `whyse.nw` in the tarball contains the command-line used to `tangle` and `weave` WHYSE.

```

18b <whyse.el 18b>≡

    '(<required packages 19a>))
Uses whyse 1 3a.

```

The Emacs Lisp Manual states, regarding the Package-Requires element of an Emacs Lisp package header:

Its format is a list of lists on a single line.

Thus, to prevent spill-over in the printed document, the *⟨required packages 19a⟩* are given on separate lines in the literate document. When the file is tangled, however, a Noweb filter will be used to ensure that all required packages are on a single line by simply removing the new lines from the following code chunk. The same principle is followed for the *⟨file-local variables 20c⟩* chunk.

```
19a ⟨required packages 19a⟩≡ (18d)
    (emacs "25.1")
    (emacsql "20230220")
    (peg "1.0.1")
    (cl-lib "1.0")
```

TODO It was said earlier that a filter of some kind is used to ensure that file-local variables are on a single line. I believe I previously had file-local variables written on separate lines which were then joined together onto a single long line to be inserted at the top of a file. I probably then learned how to write a file-local variable block for insertion at the end of the file, as I have below. The earlier statement about this chunk will need to be edited so that it isn't incorrect (no filter is used on this chunk's contents, apparently).

7 Appendices

7.1 A user-suggested functionality: w-with-project

It was suggested during early development that *<API-like functions 22>* such as w-with-project be written. An early version of such functionality is provided in w-with-project.

22 *<API-like functions 22>*≡
;; This chunk intentionally left blank at this time.

TODO Implement w-with-project

8 TESTING

TODO Adopt the ERT (Emacs Regression Tests) package to test WHYSE features as they are developed and become featureful. When a feature is implemented a test should be written which conforms to the current documentation so that regressions can be caught when changes are made.

8.1 Parsing Tests

8.1.1 Parsing tool syntax within a temporary buffer

```
23 <test-parser-with-temporary-buffer.el 23>≡
;; -*- lexical-binding: nil; -*-
(defvar w-parse-success t
  "A simple boolean regarding the success or failure of the last
  attempt to parse a buffer of Noweb tool syntax.")

<buffer parsing function 8b>

(with-temp-buffer
  (insert (shell-command-to-string
    "make -silent -file ~/src/whyse/Makefile tool-syntax"))
  (goto-char (point-min))
  (cl-prettyprint (w-parse-current-buffer-with-rules))
  (pop-to-buffer
    (clone-buffer
      (generate-new-buffer-name
        (format "<WHYSE %s> Parsing tool syntax with a temporary buffer"
          (if w-parse-success "SUCCESS" "FAILURE"))))))

;; Local Variables:
;; mode: lisp-interaction
;; no-byte-compile: t
;; no-native-compile: t
;; eval: (read-only-mode)
;; End:

Defines:
  w-parse-success, used in chunk 8b.
Uses w-parse-current-buffer-with-rules 8b and whyse 1 3a.
```

9 EDITORIAL REMARKS

1. **TODO** Interactively develop a function to pop all of the elements off a stack on top of and including the first element in that stack for which a PREDICATE function returns non-nil.
2. **TODO** Modify knoweb to use the typographic conventions of Bert Burgemeister in his Common Lisp Quick Reference.
3. **TODO** Motivating the previous item, modify autodefs.elisp and finduses.nw to work better for LISPs with multiple slots (like Maclisp / Emacs Lisp). There should be no problem differentiating between whyse the customization group, and whyse the function, and whyse the variable. This is a difficult one and probably requires manual annotation, something filters should be used for after hacking on JOSEPH S. RIEL's autodefs.elisp and NOWEB's finduses.nw!
